Bias and Scan Correction (TOVS & VTPR)

In ERA 15 NESDIS cloud cleared and nadir corrected radiances were used. The scan correction and biases were calculated monthly using model first guess profiles near radiosondes.

Scan corrections were just a global offset and applied first then a bias correction using MSU Channels 2, 3 and 4 as predictors.

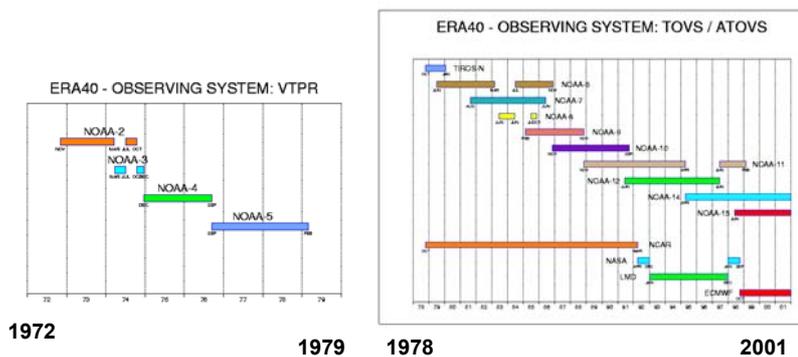

In ERA 40 raw radiances are used. The scan correction and biases are calculated on an initial monthly sample near radiosondes and are updated if there are instrumental problems.

Scan corrections are a function of latitude and applied first then the bias correction using 4 model predictors.

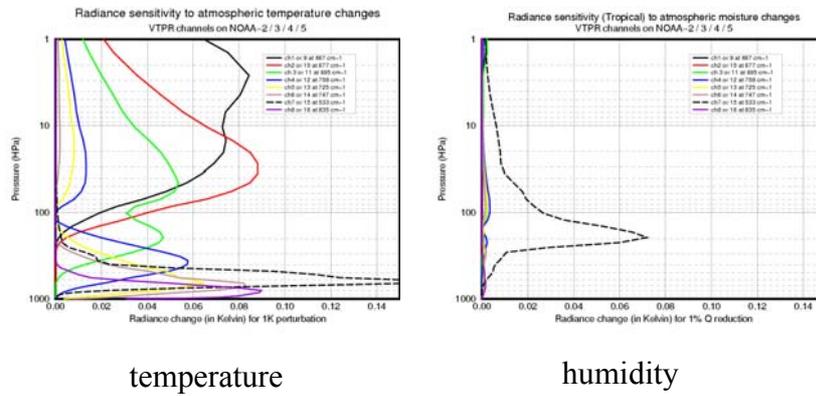

The predictors are:

- Model First Guess Thickness Z(1000-300)hPa,
- Model First Guess Thickness Z(200-50)hPa,
- Model First Guess Surface Skin Temperature,
- Model First Guess Total Column Water Vapour.

Bias and Scan Correction (SSMI)

The scan correction and biases are calculated on an initial monthly sample near radiosondes and are updated if there are instrumental problems.

Scan corrections are a function of SSMI spot position and applied first then the bias correction using 4 model predictors.

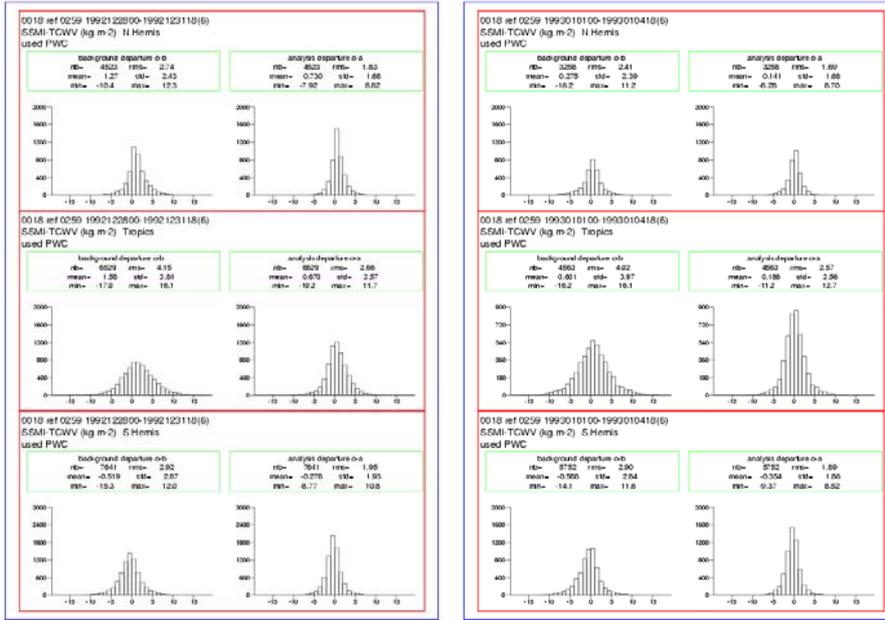

The predictors are:

- Model First Guess Mean Sea Level pressure,
- Model First Guess 10 m wind speed,
- Model First Guess Surface Skin Temperature,
- Model First Guess Total Column Water Vapour.

Conclusions

PAOBs are needed prior to the TOVS period in the Southern Hemisphere.

This is the first time that raw radiances have been used in a re-analysis with many satellite instruments.

The new bias predictors have removed the need for monthly updating of coefficients. However the tuning is based on the quality of the radiosondes used in the assimilation.

Instrument behaviour is still a problem. There are short periods where some instruments are unable to be used. Often when the instrument had recovered it requires new bias correction coefficients.

If there is only one satellite in the assimilation and a problem occurs with a satellite instrument. It may not be detected easily.

ERA 40 should provide information to calibrate the radiance measurements from the instruments used. Hence future reanalysis will be easier. However some further effort will be required.
