

Monitoring the atmosphere and observing system: ERA-40 and GEMS

Adrian Simmons

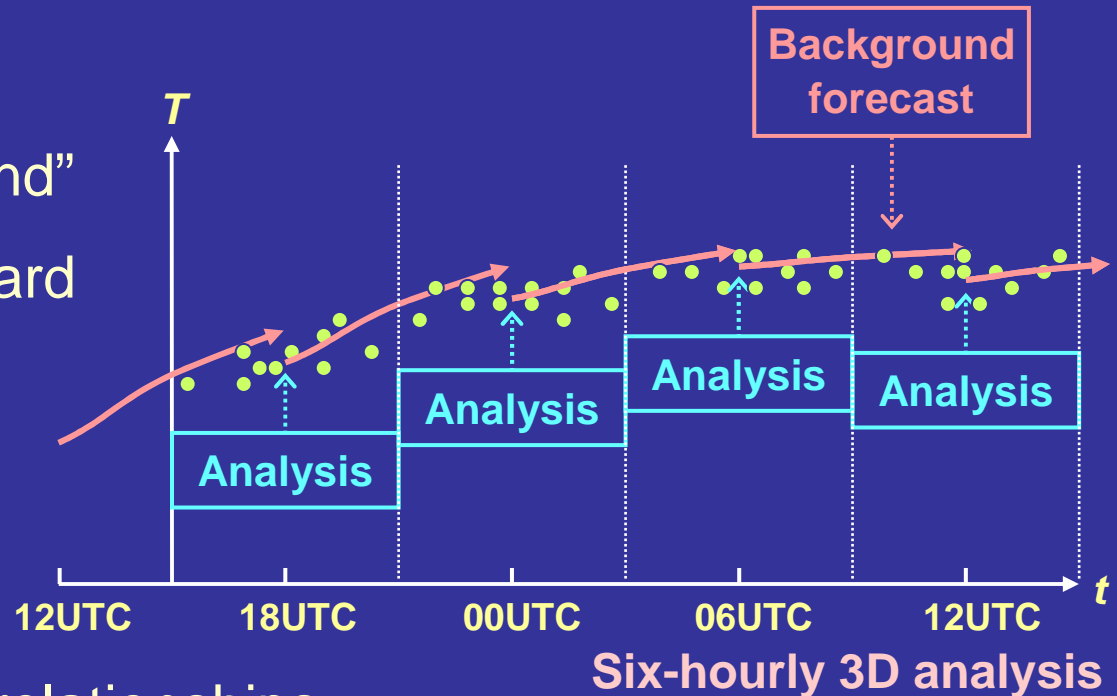

European Centre for Medium-Range Weather Forecasts

**with thanks to all who contributed to ERA-40
and the planning of GEMS**

Data assimilation

- **Combines information from**

- Recent observations
- A short-range “background” forecast that carries forward information extracted from earlier observations
- Statistics
- Dynamical and physical relationships

**to produce the “most probable”
estimate of the state of the atmosphere**

Data assimilation provides:

- **Initial states for numerical weather prediction**
- **A historical record of the state of the atmosphere**
- **A route to improved determination of
atmospheric composition**
- **Monitoring of the observing system**

Data coverage

09UTC – 15UTC

5 June 2004

Changes over time

- The observing system has changed substantially since the 1950s
- Data analysis methods and assimilating models, and the computers systems used to run them, have changed substantially over the same period

Princeton, 1950

Reading, 2002

Reanalysis

- **Operational products vary in quality over time due to changes:**
 - in the observing system
 - in the data assimilation systems
 - in the atmosphere itself
- **Reanalysis provides products of more uniform quality by applying a fixed, modern data assimilation system to multi-decadal sets of observations**
- **ERA-40 (September 1957 to August 2002) is the latest reanalysis to be completed**

Principal external sources of support for ERA-40

European Union

US National Center for Atmospheric Research (NCAR)

US National Centers for Environmental Prediction (NCEP)

Fujitsu Ltd

EUMETSAT

Japan Meteorological Agency

Chinese Academy of Sciences

PCMDI, USA

World Climate Research Programme

Global Climate Observing System

And several providers of particular observational datasets

***In-situ* (“conventional”) observations for ERA-40**

- Radiosonde and pilot-balloon soundings 1957 - 2002
- Surface data from land stations and ships 1957 - 2002
- Flight-level data from commercial aircraft 1973 - 2002
- Surface data from ocean buoys 1979 - 2002

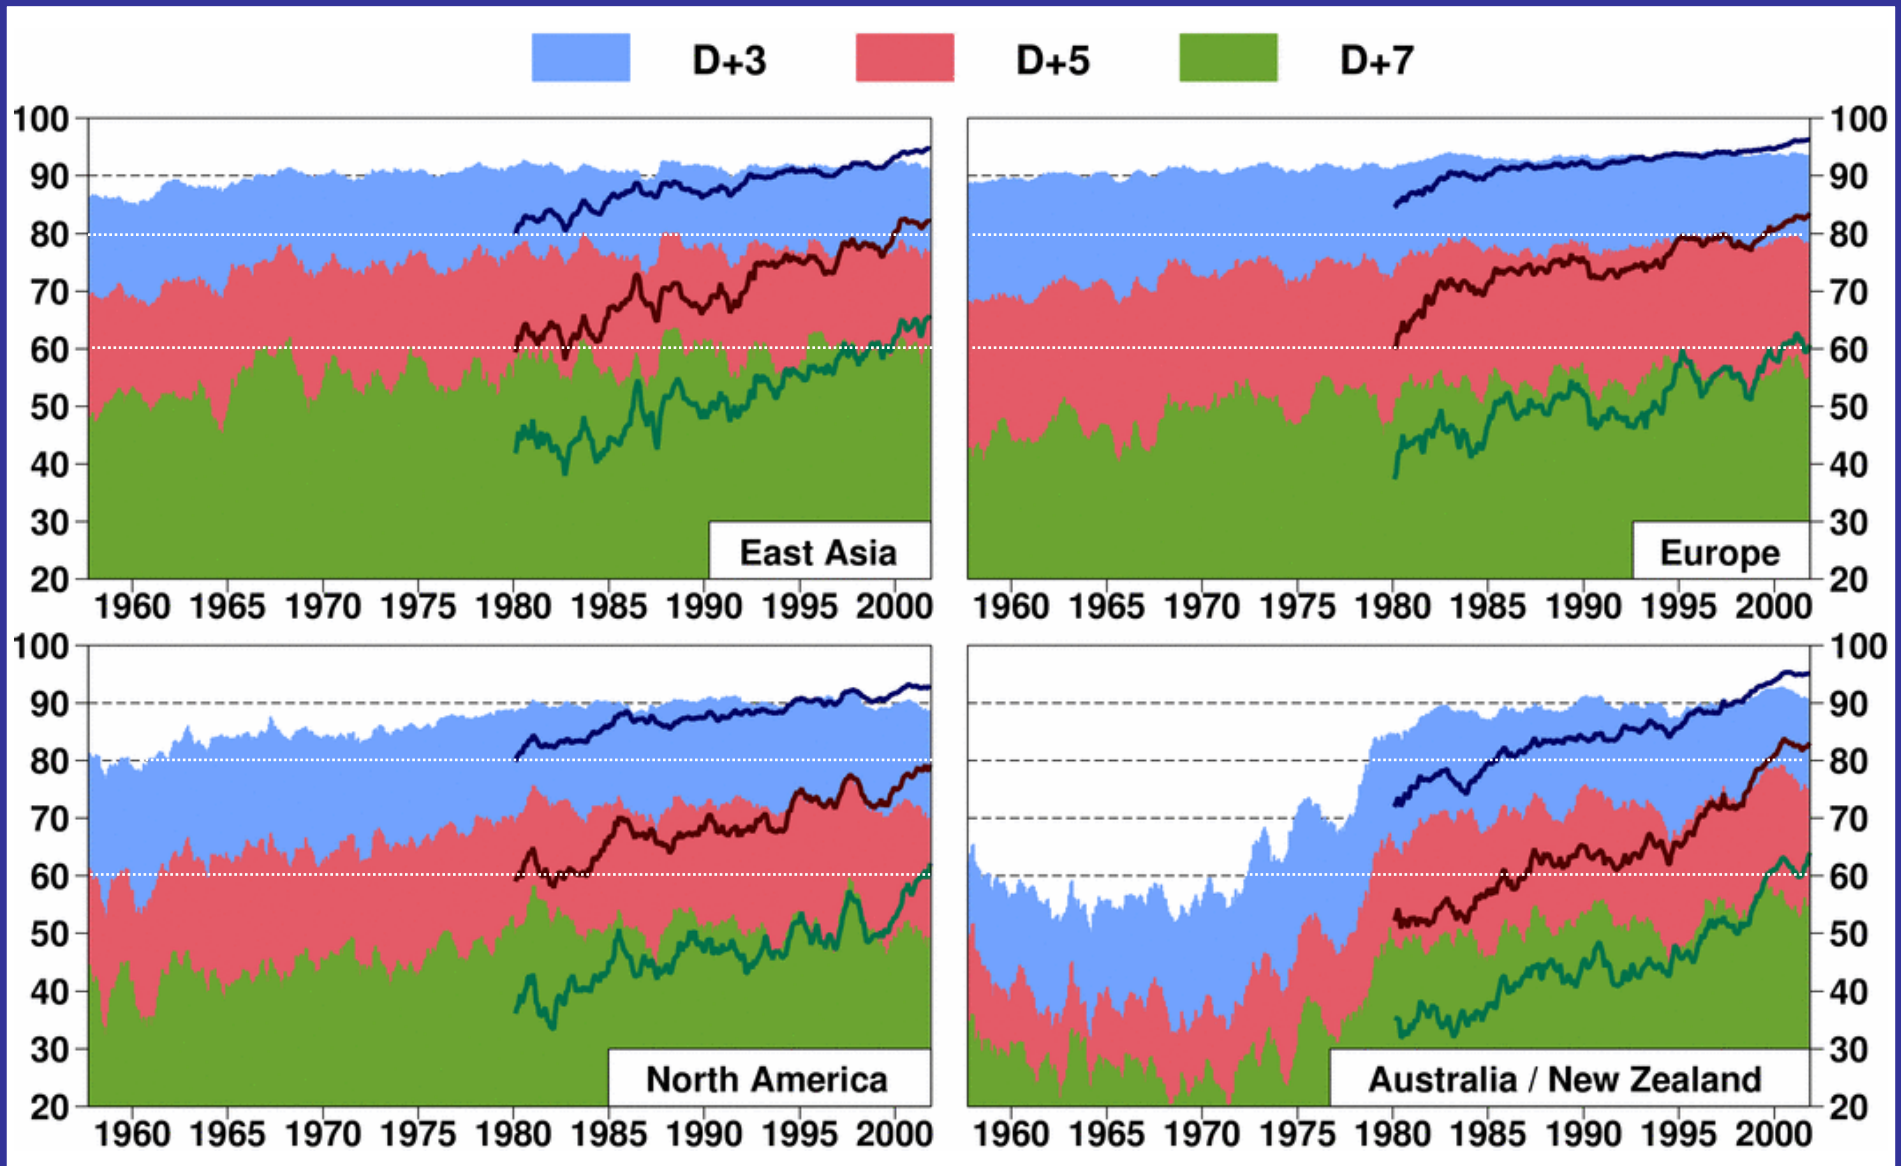

Satellite data for ERA-40

- NOAA VTPR radiances 1973 - 1978
- NOAA TOVS/ATOVS radiances 1979 - 2002
- Winds from geostationary orbit 1979 - 2002
- TOMS/SBUV ozone retrievals 1979 - 2002
- SSM/I radiances 1987 - 2002
- ERS scatterometer & altimeter 1991 - 2002

RMS fit (hPa) of 6h background forecast to SYNOP and SHIP surface-pressure data over the extratropical southern hemisphere

GEMS: Global and regional Earth-system Monitoring using Satellite and in-situ data

- **A multi-partner EC-funded R&D programme to develop:**
 - **Global modelling and data assimilation for greenhouse gases, reactive gases and aerosols**
 - **An integrated production system for the above**
 - **Regional modelling, assimilation and prediction of air quality**

which will enable:

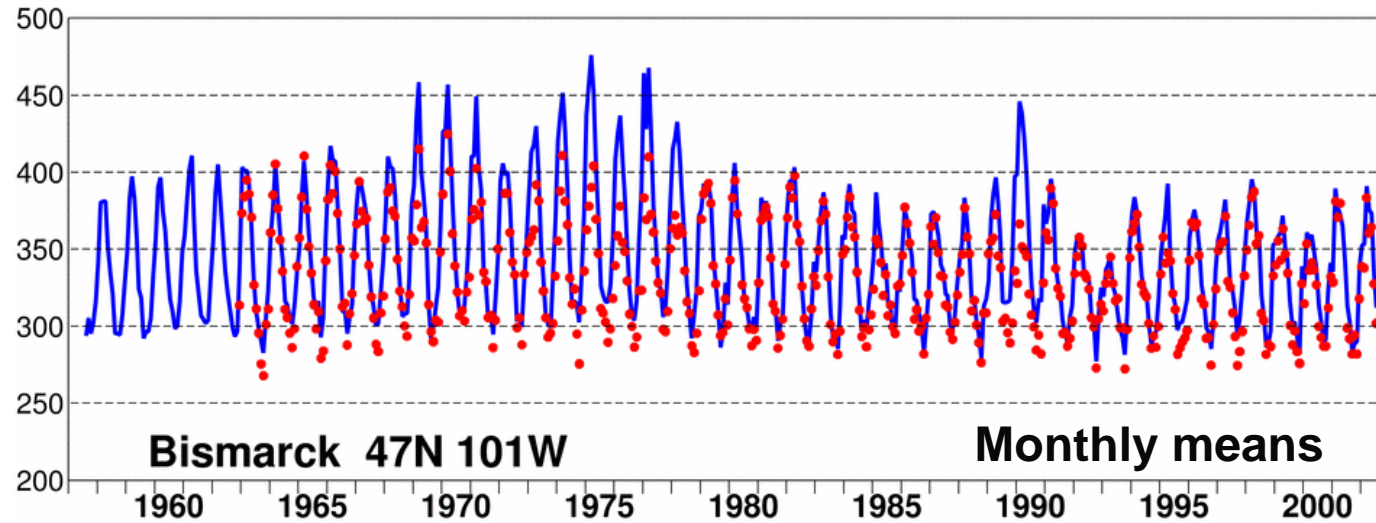

- **Daily global monitoring of atmospheric composition**
- **Better daily regional air quality forecasts**
- **Estimation of surface fluxes for CO₂ and other species**
- **More comprehensive reanalysis products**

Aerosol: satellite image of desert dust

A massive sandstorm blowing off the northwest African desert has blanketed hundreds of thousands of square miles of the eastern Atlantic Ocean with a dense cloud of Saharan sand. The massive nature of this particular storm was first seen in this SeaWiFS image acquired on Saturday, 26 February 2000 when it reached over 1000 miles into the Atlantic. These storms and the rising warm air can lift dust 15,000 feet or so above the African deserts and then out across the Atlantic, many times reaching as far as the Caribbean where they often require the local weather services to issue air pollution alerts as was recently the case in San Juan, Puerto Rico. Recent studies by the U.S.G.S. (http://catbert.er.usgs.gov/african_dust/) have linked the decline of the coral reefs in the Caribbean to the increasing frequency and intensity of Saharan Dust events. Additionally, other studies suggest that Sahalian Dust may play a role in determining the frequency and intensity of hurricanes formed in the eastern Atlantic Ocean (<http://www.thirdworld.org/role.html>)

Aerosol: model source-term for salt

Sunday 15 October 2000 12UTC ECMWF Forecast t+120 VT: Friday 20 October 2000 12UTC Surface: **

Aerosol: Stratospheric warming due to sulphate aerosol from volcanic eruptions

MSU-4 data analyzed by Mears et al. (2003)

ERA-40 equivalent from Santer et al. (2004)

Implications for computing

- **Good balance between HPC, data handling, servers, web services and networks is essential for reanalysis**
- **Reanalysis is a time critical HPC application, running at lower resolution and on lower number of processors than operations**
- **ERA-40 took 5-10% of Fujitsu resources for two years and produced ~70 Terabytes of data**
- **GEMS will start at reanalysis resolution; chemistry calculations are computationally demanding**
- **Elements of GEMS will find their way into high-resolution operations – demand for HPC will increase**

In conclusion

- **The last user job to run on ECMWF's Cray C90 was the final step of ECMWF's first reanalysis, ERA-15**
- **The last user job to run on ECMWF's Fujitsu VPP systems was the final step of ERA-40**
- **ECMWF plans to carry out a new reanalysis covering the period 1989-2008**
