WP2 breakout discussion summary

ERA-CLIM2 General Assembly, Dec 2015.

WP2 discussion topics

- Scientific discussion on selected topics:
 - Estimation of coupled covariances by CERA/METO/CMCC.
 - ensemble generation CMCC/ECMWF/MERCO
- Code merging/integration updates.
- Future WP2 coordination meeting.
- Potential ERA-CLIM3 work on developments for coupled reanalysis.

Coupled error covariances:

- Discussed innovations-based method.
- Results from METO show that, despite strong variable-variable correlations, error-error correlations are small, at least for some variable-pairs such as T2m/SST and wind-speed/SST.
- Would be good for UREAD to calculate similar from CERA system which requires output of SST nudging term from the first outer loop.

Ensemble generation:

- ECMWF, CMCC, MERCO all have implemented various aspects of this.
- Suggest that they be compared/combined.
- Would be useful if the groups use NEMO3.6 so that developments can be shared.
- Need to define a protocol for assessing/comparing different perturbation methods.

Plan for next year

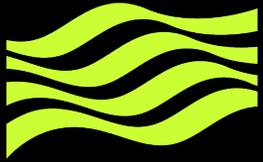

Code merging/integration:

- MERCO work on anamorphosis: modular code available next year, and recommendations/ideas for implementation in variational context.
- Continue with NEMOVAR code merging work by METO/CERFACS/INRIA/ECMWF.

Other development work: LSCE/UVSQ continue to discuss developments/inputs with ECMWF. Other R&D work to continue.

Future WP2 coordination meeting:

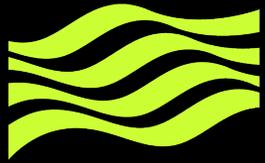

- Suggest to have one in ~6 months time.
- Have it in conjunction with another meeting. 2 suggestions:
 - GODAE OceanView joint DA-TT and MEAP-TT workshop in July 2016.
 - WMO workshop on coupled DA. Location/time needs to be determined.

Met Office

Potential future project:

- Focus for the development work will be determined to some extent by the relationship with the Copernicus climate service reanalysis. A more clearly defined relationship with Copernicus would help. For example, would a future project focus on: full 20th Century reanalysis, or a preSat run, or include upper air, ...?
- Most of the existing work in WP2 will need integrating/ implementing in the CERA system.
- Would be useful to have more atmospheric expertise within the development WP.

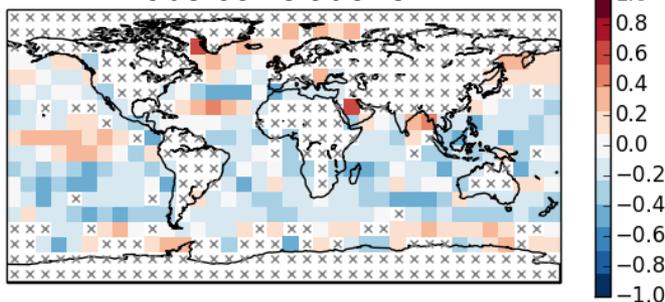

Met Office

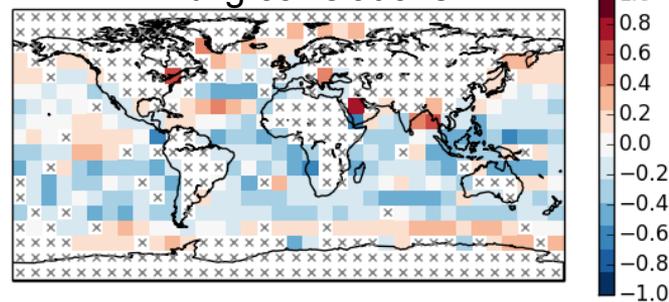

Coupled error covariances:

- Discussed innovations-based method. Results from METO show that, despite strong variable-variable correlations, error-error correlations are weak, at least for some variable-pairs such as T2m/SST.
- Would be good to calculate similar from CERA system which requires output of SST nudging term from the first outer loop [Action].
